

What Host name based tagger is done for

You can define a tagger that will use the Host name to automatically add host templates to detected objects. The common tagger named regexp-tags can load new ip range rules with modules.

How to define a new Regexp rule

For each Regexp rule, you will need to define a new module and add it in the regexp-tags tagger configuration.

You can copy the sample module `/etc/shinken/modules/sync-regexp-tag.cfg` into a new file name and edit it:

```
define module{
    module_name      sync-regexp-tag-windows
    module_type      sync-regexp-tag
    matched_prop     host_name
    matched_regexp   .*srvwin.*
    method           append
    property         use
    value            windows
}
```

For each Regexp rule, you will need to define a new module and add it in the regexp-tags tagger configuration.

You can copy the sample module `/etc/shinken/modules/sync-regexp-tag.cfg` into a new file name and edit it:

The properties are:

- **module_name**: must be unique in the modules
- **module_type**: must be equal to sync-regexp-tag
- **matched_prop**: the property that we will match. By default the property is host_name (Name of the host object)
- **matched_regexp**: Regexp that the object must match to activate this rule
- **method**: how you want to modify your detected object:
 - **replace**: put the value if not another one is in place
 - **append**: add the value at the END of the host templates
 - **prepend**: add the value at on the BEGINING of the host templates
 - **set**: just the value, erase what was before.
- **property**: which host property to change. By default the property is "use" (host templates)
- **value**: which value to set/append/prepend/replace

Then you must edit the ip-tags tagger definition to link your new module in the file `/etc/shinken/taggers/regexp-tags.cfg`:

```
define tagger {
    tagger_name      regexp-tags
    order            1
    modules          sync-regexp-tag,sync-regexp-tag-windows
    description      This tagger will tag host based on the host_name
}
```

Then you must restart your shinken-synchronizer daemon.
