

Taggers are tools that will read all detected hosts (automatic and manual hosts) and will match them to rules. If the host is matching a rule, it will modify it (like add a new host template). Currently two kind of taggers are available:

- [IP range based tagger](#)
- [Host name based tagger](#)

You can define as many rules as you need.

Each tagger will apply one after the other. Each tagger have an *order* parameter that define in each order they will read and modify objects.
